Subject: Automated Efficiency Tracking for Fuel Depot Operations

This memo explains the operational efficiency tracking tool developed for the fuel depot network. The tool compares each depot's actual fuel output against its expected target output and produces a clear performance status for each site. In this case, the tool was applied to three depots: Nairobi Fuel Depot, Mombasa Fuel Depot, and Kisumu Fuel Depot. The purpose was to create a simple way of showing whether each depot is performing normally, showing early signs of concern, or requiring urgent management attention.

Automating efficiency tracking is important because manual checks can be slow, inconsistent, and prone to error. In a busy fuel depot environment, managers may receive output figures from different sites at different times, making it difficult to quickly compare performance. When this process is handled manually, delays can occur before underperforming depots are identified. An automated approach allows the same calculation method to be applied to every site, which improves consistency and reduces the risk of overlooking operational problems.

The tool works by taking the actual output for each depot and comparing it with the planned target. It then converts that comparison into a percentage score. For example, a depot that delivers 7,200 litres against a target of 10,000 litres has achieved 72% efficiency. The tool then places each depot into one of three categories: "Critical" for performance below 70%, "Warning" for performance from 70% to 89%, and "Normal" for performance of 90% or higher. These categories make the results easier for managers to interpret without needing to study raw numbers.

The results show that Mombasa Fuel Depot is performing well, with an efficiency score of 91% and a "Normal" status. Nairobi Fuel Depot achieved 72%, which places it in the "Warning" category and suggests that management should review its performance before it worsens. Kisumu Fuel Depot achieved 62%, which places it in the "Critical" category and indicates that immediate attention is needed. This allows management to focus first on the depot with the most serious performance issue instead of reviewing all sites manually.

This tool helps identify problems faster because it turns raw operational figures into clear decision-making information. Instead of waiting for several manual reports, managers can quickly see which depot is on track and which one needs support. This can help improve response time, reduce delays, and support better use of staff, transport, storage, and supply resources.

I recommend that this tool be deployed within the Operations or Dispatch Department as a simple weekly performance tracker. Each depot can submit its actual fuel output and target output at the end of the week. The department can then use the tracker to generate a short performance report for management review. Over time, the same approach could be expanded to include more depots, daily reporting, and additional

indicators such as delivery delays, stock shortages, vehicle turnaround time, and customer order fulfilment. This would give managers a faster and clearer view of operational performance across the fuel depot network.
